

CANDY DIALOGUE ENGINE

Inputs

1.0.0

The [Setup](#) guide instructed you to add an input to your Godot project: [Dialogue_Advance](#).

However, Candy DE can actually make use of several more inputs.

The actual names of inputs are also irrelevant: they are assigned to variables in [Candy_Engine.gd](#), so you can name inputs anything you want.

The input variables are the following:

- | | |
|-------------------------------|--|
| input_advance_dialogue | → Once a spoken line has been displayed on screen, this input makes dialogue continue. |
| input_speed_dialogue | → When using the typewriter effect, this input speeds up the writing speed to a value of your choosing. |
| input_slow_dialogue | → When using the typewriter effect, this input slows down the writing speed to a value of your choosing. |
| input_skip_dialogue | → When using the typewriter effect, this input makes the entire text display instantly. |

Note that the same input can be assigned to `input_advance_dialogue` and either `input_speed_dialogue`, `input_slow_dialogue`, or `input_skip_dialogue`. This way, the same key can both speed up/slow down/skip the typewriter effect, and also advance to the next line.

These variables are found in the "Settings" region of [Candy_Engine.gd](#), but are exported by default (`@export`), meaning that you can edit them directly in the Inspector in Godot. See the [Typewriter Effect](#) guide for more information.

To prevent an instance of the dialogue engine from reacting to inputs, you can set its [input_enabled](#) variable to 'false'. This variable is found in the "Variables" region of the script, and is also exported. You can set this to 'true' or 'false' by default, or toggle it at runtime.

No dedicated input is provided for suspending (pausing) dialogue: you should instead write a function that toggles [dialogue_suspended](#) on specific engine instances. See the [Suspend Dialogue](#) guide for more information.
